

# Production of large forged parts (steels, stainless steels and nickel-based superalloys)

Prof. Marcello Gelfi - Università degli Studi di Brescia

- Introduction of Brescia University and Metallurgy Group.
- Large steel forgings production route.
- The effect of ingot internal cleanness and chemical segregations on the quality of forgings → case studies.
- The effect of heat treatments and forging parameters on the final microstructure and mechanical properties  $\rightarrow$  case studies.
- Non-conventional application of PH heat treatment on 625 Nibased superalloy forged bars for oil & gas field applications.
- Final discussion/questions.

### Brescia - Lombardy (Italy)

- 200,000 inhabitants in Town, 1,100,000 in Province
- 40% of the manufacturing capabilities of Milan with 10% population
- Unique economy: 90.000 companies
- Lombardy: Top 3 GDP region in Europe with London and Paris

#### **Coatings characterization**

#### Industry collaborations

#### Various forms of collaboration with companies:

The Metallurgy group is involved in several of these activities (approx. 40-50 contracts/year).

# Large steel forgings

#### Large steel forgings

#### Two factors related to steel ingots can affect the forgings quality:

- 1. Non-metallic macro-inclusions.
- 2. Micro- and macro-segregations.

Non-metallic inclusions with size of few tens of microns are always present in steel (deoxidation products).

Alumina-type inclusions remain in the liquid steel and tend to agglomerate during casting (e.g. at the nozzle exit) creating a problem, known as nozzle clogging.

An even more serious problem happens if these alumina-type agglomerates pass from the ladle to the mold, remaining entrapped in the solidified ingot  $\rightarrow$  indigenous macro-inclusions.

# OM image of alumina-type agglomerates

# SEM image of crack nucleated from alumina-type macro-inclusion

Other types of macro-inclusions can come from external sources (e.g. refractories, mold flux,..)  $\rightarrow$  exogenous macro-inclusions.

Data from 35 ton-ingots scrapped for macroinclusions (75 ingots).

#### 40% of ingot scraps is due to entrapment of mold flux (powder).

29/01,	/2020
--------	-------

**NB:** mold flux macro-inclusions can be **easily detected** as they have specific composition and typical shape and distribution.

Spectrum	0	Na	Mg	Al	K	Ca	Fe
1	39.03	1.46	2.82	34.97	2.48	3.55	15.68

To limit this problem, bags of mold powder are prepared into the mold suspended at a certain height to avoid premature release.

**<u>CASE STUDY</u>**: numerical modelling can be conveniently applied to simulate the liquid metal flow during the mold filling.

This can help evaluating the risk of powder entrapment and defects formation.

A 4-mold system for 19-ton round ingots of AISI 4140 steel was considered.

For this purpose, it is crucial using a full mold geometry, respect to conventional simplified models.

Pouring basin (trumpet) and running system were included in the model, considering real geometry and refractory materials.

#### Full model

29/0	1/20	20
------	------	----

Full model results show that the steel, entering the mold at high speed, reaches a height of 630 mm  $\rightarrow$  risk to break the suspended powder bags  $\rightarrow$  premature release of mold powder.

Simplified model completely neglects this problem.

#### Liquid steel entering the mold: full model vs. simplified model

#### Liquid metal tangential velocity after 24 s and 930 s

29/01/2020

![](_page_22_Picture_0.jpeg)

![](_page_22_Picture_2.jpeg)

The Weber number,  $W_e$  can be calculated to estimate the risk for powder entrapment  $\rightarrow$  if  $W_e > 12.3$  this risk increases.

$$W_{e} = \frac{u_{steel}^{2} \cdot \rho_{steel}}{\sqrt{\gamma \cdot g \cdot (\rho_{steel} - \rho_{slag})}}$$
where:  

$$u_{steel} = \text{tangential steel velocity}$$

$$\rho_{steel} = \text{steel density}$$

$$\rho_{slag} = \text{slag density}$$

$$\gamma = \text{slag-steel interfacial tension}$$

$$g = \text{gravity constant}$$

![](_page_23_Picture_0.jpeg)

![](_page_23_Picture_2.jpeg)

Two main factors related to steel ingots affect forgings quality:

- **1. Non-metallic macro-inclusions.**
- 2. Micro- and macro-segregations.

![](_page_23_Figure_6.jpeg)

![](_page_24_Picture_0.jpeg)

![](_page_24_Picture_2.jpeg)

Hot deformation processes align these interdendritic chemistry variations into **micro-segregation bands**, parallel to deformation.

 $\rightarrow$  alternating regions of high and low concentration of solute.

![](_page_24_Figure_5.jpeg)

# Mn and C content fluctuations across segregation bands of AISI 4140 rolled steel

![](_page_25_Picture_0.jpeg)

![](_page_25_Picture_2.jpeg)

**<u>CASE STUDY</u>**: the effect of segregation bands on mechanical properties have been studied on heavy forgings in AISI 8630 steel.

Two forgings with different level of segregations were considered.

![](_page_25_Figure_5.jpeg)

	C	Mn	Si	Cr	Ni	Мо	V	Cu	CE
HS-forging 1	0.31	1.07	0.31	0.98	0.83	0.42	0.042	0.05	0.84
LS-forging 2	0.322	1.08	0.3	0.96	0.82	0.4	0.027	0.13	0.84

![](_page_26_Picture_0.jpeg)

![](_page_26_Picture_2.jpeg)

The alternate light/dark bands revealed by Nital2 etching on HSforging 1 samples are clearly more intense respect to LS-forging 2.

![](_page_26_Picture_4.jpeg)

#### HS-forging 1 (High)

LS-forging 2 (Low)

29/01/2020

![](_page_27_Picture_0.jpeg)

![](_page_27_Picture_2.jpeg)

Light bands with low alloying elements have lower hardenability → anomalous microstructure after quenching and tempering.

![](_page_27_Figure_4.jpeg)

![](_page_27_Figure_5.jpeg)

![](_page_27_Figure_6.jpeg)

#### HS-forging 1 (High)

29/01/2020

![](_page_28_Picture_0.jpeg)

![](_page_28_Picture_2.jpeg)

#### In HS-forging 1, strong segregation banding significantly reduce both the tensile strength and the impact energy absorption.

	HV <sub>300g</sub> light band	HV <sub>300g</sub> dark band	UTS (MPa)	YS (MPa)	КV <sub>-46°С</sub> (J)
HS-forging 1	219±9	249 ± 3	749 ± 13	589 ± 9	31
LS-forging 2	245 ± 5	265 ± 6	827 ± 14	$657 \pm 11$	123

![](_page_28_Picture_5.jpeg)

HS-forging 1 - Charpy test fracture surface and etched cross section

![](_page_29_Picture_0.jpeg)

High pre-forging temperatures combined with large reductions (deformation ratios > 5:1) can help to homogenize the material.

#### Microstructure and impact energy of AISI 8630 steel forgings (longitudinal samples)

29/01/2020

![](_page_32_Picture_0.jpeg)

![](_page_32_Picture_2.jpeg)

Heat treatments are also very important to determine the final microstructure and mechanical properties of heavy forgings.

Typically, special grades steel forgings are provided in quenched and tempered conditions.

![](_page_32_Picture_5.jpeg)

![](_page_33_Picture_0.jpeg)

![](_page_33_Picture_2.jpeg)

**<u>CASE STUDY</u>**: the proper choice of quenching medium is crucial to guarantee the expected microstructure and mechanical properties, also minimizing the risk of thermal cracks.

Numerical modelling is helpful in simulating forgings cooling to forecast the microstructure on the whole thickness.

To obtain reliable results, the heat transfer coefficient, h (W/m<sup>2</sup>K) of quenching medium has to be properly defined.

	Air	Oil	Water	Brine
No circulation of fluid or agitation of piece	0.02	0.25-0.30	0.9-1.0	2
Mild circulation (or agitation)		0.30-0.35	1.0-1.1	2-2.2
Moderate circulation		0.35-0.40	1.2-1.3	
Good circulation		0.4-0.5	1.4-1.5	
Strong circulation	0.05	0.5-0.8	1.6-2.0	
Violent circulation		0.8-1.1	4	5

![](_page_34_Picture_0.jpeg)

![](_page_34_Picture_2.jpeg)

In this example, the h coefficient was determined by experimental tests carried out on a AISI 4140 steel block equipped with n°4 thermocouples embedded into the material at different depths.

# Simulated temperatures in the cross section of steel block after 720 s and 1800 s

29/01/2020

![](_page_36_Picture_0.jpeg)

![](_page_36_Picture_2.jpeg)

The model calibration was obtained by fitting the experimental temperatures vs. time curves with the simulated one, at different depths in the steel block.

![](_page_36_Figure_4.jpeg)

![](_page_37_Picture_0.jpeg)

![](_page_37_Picture_2.jpeg)

The model was successfully applied on a real forging for wind turbine in AISI 4140 steel.

The expected microstructure and hardness were confirmed by metallographic analysis.

![](_page_37_Figure_5.jpeg)

![](_page_37_Picture_6.jpeg)

![](_page_37_Picture_7.jpeg)

![](_page_38_Picture_0.jpeg)

![](_page_38_Picture_2.jpeg)

**<u>CASE STUDY</u>**: the effect of the final solution annealing on the microstructure of AISI 316L forged bars was studied.

316L microstructure can suffer of a problem named Abnormal Grain Growth (AGG)  $\rightarrow$  orange peel defects, false positives in UT,...

![](_page_38_Figure_5.jpeg)

![](_page_39_Picture_0.jpeg)

![](_page_39_Picture_2.jpeg)

At the end of bar forging, two different options were considered:

- 1) Solution annealing (1050°C-3h) followed by water quenching.
- 2) Direct water quenching.

Samples were cut at the bars end in 3 positions (surface,  $\frac{1}{2}$  radius, center), polished and electrolytic etched with 60% HNO<sub>3</sub>.

Microstructure grain size was measured according to ASTM E-112.

Bars	φ initial (mm)	φ final (mm)	Reduction (%)	Pyrometer final temperature (°c)	Heat treatment
1	450	360	36%	900°C	1050°C 3h + water quenching
2	450	360	36%	900°C	Direct water quenching

![](_page_40_Picture_0.jpeg)

![](_page_40_Picture_2.jpeg)

FEM simulation of forging process showed that at the surface the temperature dropped down to ~  $900^{\circ}$ C (close to the tips), while at the center it progressively increased above 1200 °C.

![](_page_40_Figure_4.jpeg)

#### Simulated temperatures distribution in the bar at different reduction steps

![](_page_41_Picture_0.jpeg)

![](_page_41_Picture_2.jpeg)

![](_page_41_Figure_3.jpeg)

Bar 1 (solution annealing + quenching)

![](_page_42_Picture_0.jpeg)

SYNCHROTRON THAILAND CENTRAL LAB

**NB**: partial recrystallization can be confused with AGG.

 $\rightarrow$  double electrolytic etching: 60% nitric acid + 10% oxalic acid, recrystallization twins in AGG grains are revealed.

Bar 1

![](_page_42_Figure_6.jpeg)

#### Bar 2

![](_page_42_Figure_8.jpeg)

Center

![](_page_42_Picture_10.jpeg)

![](_page_43_Picture_0.jpeg)

![](_page_43_Picture_2.jpeg)

Solution annealing vs. direct quenching has the advantage to ensures full recrystallization everywhere in the bar cross-section.

But, it leads to grain coarsening and AGG, especially at the bar center, where maximum forging temperatures are developed.

![](_page_43_Figure_5.jpeg)

#### ASTM grain size distribution in the two forged bars

![](_page_44_Picture_0.jpeg)

![](_page_44_Picture_2.jpeg)

**<u>CASE STUDY</u>**: the 625 alloy is an excellent corrosion resistance material for Oil and Gas field normally supplied in two conditions:

Grade 1 – Annealed

Grade 2 – Solution Annealed

The aim of this study was to evaluate the effect of precipitation hardening (PH) heat treatment on mechanical and corrosion resistance (e.g. SCC and SSC) of 625 alloy forged bars.

For this purpose 625 alloy forged bars with 3 different diameters: 152 mm, 203 mm, 254 mm (6 - 8 - 10 in.) have been produced.

Ni	Cr	Мо	Nb + Ta	Fe	Ti	С	Mn	Si	Al	Со
58.0 min.	20 - 23	8 -10	3.15 -4.15	5.0 max.	0.40 max.	0.10 max.	0.50 max.	0.50 max.	0.40 max.	1.0 max.

#### Forging

#### Final product

29/01/2020

![](_page_46_Picture_0.jpeg)

![](_page_46_Picture_2.jpeg)

Preliminary tests were performed on samples collected from top/bottom of bars at ½ radius position to find out the optimal heat treatment parameters.

Each samples set was composed of: tensile, Charpy, hardness and ASTM G28 specimens.

![](_page_46_Figure_5.jpeg)

![](_page_47_Picture_0.jpeg)

![](_page_47_Picture_2.jpeg)

HTs parameters were chosen according to literature and JMatPRO, aiming at maximizing gamma double prime  $\gamma''$  (Ni<sub>3</sub>Nb) precipitation.

![](_page_47_Figure_4.jpeg)

![](_page_47_Figure_5.jpeg)

![](_page_48_Picture_0.jpeg)

![](_page_48_Picture_2.jpeg)

HT conditions	Annealing temperature (°C)	Ageing temperature (°C)	Ageing time (h)
1	980	650	10
2	1010	650	10
3	980	660	10
4	1010	660	10
5	980	670	10
6	1010	670	10
7	980	650	16
8	1010	650	16
9	980	660	16
10	1010	660	16
11	980	670	16
12	1010	670	16

#### PH heat treatment conditions

![](_page_49_Picture_0.jpeg)

![](_page_49_Picture_2.jpeg)

![](_page_49_Figure_3.jpeg)

![](_page_50_Picture_0.jpeg)

![](_page_50_Picture_2.jpeg)

The heat treatment was performed on n°3 forged bars with different dimeters in an industrial furnace, as designed:

- annealing at 1010  $^\circ C$  for 1 hour,
- ageing at 670  $^{\circ}$ C for 16 hours followed by water quenching.

![](_page_50_Picture_6.jpeg)

![](_page_51_Picture_0.jpeg)

![](_page_51_Picture_2.jpeg)

OM analysis performed on top/bottom of the 3 bars, at the surface, ½ radius and center, gave the following results:

- even recrystallized microstructure with ASTM G6 grains;
- no continuous network of secondary phases (Laves, carbides..).

![](_page_51_Figure_6.jpeg)

![](_page_52_Picture_0.jpeg)

![](_page_52_Picture_2.jpeg)

SEM-EDS analysis identified the isolated second-phase particles at grain boundaries as Nb-rich carbides.

![](_page_52_Picture_4.jpeg)

Result Type	Weight %			
Elements	Spectrum			
С	25.80			
Cr	16.24			
Fe	2.64			
Ni	43.23			
Nb	4.61			
Мо	7.70			

![](_page_53_Picture_0.jpeg)

![](_page_53_Picture_2.jpeg)

TEM diffraction patterns confirmed the presence of one phase within the grains compatible with  $\gamma''$  phase (average size = 3.6 nm).

![](_page_53_Picture_4.jpeg)

29/01/2020

![](_page_54_Picture_0.jpeg)

![](_page_54_Picture_2.jpeg)

For all bar diameters and positions, the PH heat treatment significantly increases tensile strength and hardness.

![](_page_54_Figure_4.jpeg)

![](_page_55_Picture_0.jpeg)

## Forging parameters and HTs OF SYNCHROTRON

On the other side, the expected decrease of ductility, expressed in terms of A%, Z% and absorbed impact energy, was quite limited.

![](_page_55_Figure_3.jpeg)

![](_page_56_Picture_0.jpeg)

![](_page_56_Picture_2.jpeg)

From the corrosion point of view, the age-strenghtened 625 alloy gave excellent results, comparable to the annealed condition.

Every bar passed the C-ring test, performed in the SCC- NACE VII environment  $\rightarrow$  no cracks were detected after more than 2000 h.

Test	Number of bar materials	Total Number of alloy 625 specimens	Temperature (°C)	Test duration (hours)	Environment	Applied stress (%AYS)
SSC NACE VII	3	9 C-ring + 3 calibration C- ring	205	2160	180000 ppm Cl⁻ ppCO₂: 35 bar ppH₂S: 35 bar	100

![](_page_56_Picture_6.jpeg)

![](_page_57_Picture_0.jpeg)

![](_page_57_Picture_2.jpeg)

The aged 625 alloy also passed the Dead weight test carried out to evaluate the resistance to SSC (sulphide stress corrosion cracking).

After more than 700 h, stereo-microscope analysis of samples surface showed the absence of cracks.

Test	Alloy 625	Number of alloy 625 specimens	Temperature (°C)	Test duration (hours)	Test gas	Solution	Applied stress (%AYS)
	1.5	3					
SSC		3	24	720	1 bar H <sub>2</sub> S	NACE A	90
		3					

![](_page_57_Picture_6.jpeg)

![](_page_58_Picture_0.jpeg)

![](_page_58_Picture_2.jpeg)

In conclusion:

- The optimized precipitation hardening (PH) parameters were defined for 625 alloy forged bars.
- PH treatment produced a strong increase of yield strength respect to the annealed condition, without loss of ductility.
- NACE SCC and SSC corrosion tests were successfully passed.
- Mechanical and corrosion properties have not been influenced by bar diameter (from 6 to 10 inches).
- 625 alloy forged bars in PH condition are suitable for Oil & Gas applications.

![](_page_59_Picture_0.jpeg)

![](_page_59_Picture_1.jpeg)
